

0.60, was measured in a helium polarimeter between the two cyclotrons. Reaction  ${}^6\text{Li}$  particles were momentum analyzed using the QDDM magnetic spectrograph and detected using the helical wire counter and two plastic scintillators. In order to discriminate between reaction  ${}^6\text{Li}$  particles and  $\alpha$ -particles, the helix voltage was reduced about 300 V from its normal operating level, thus allowing the helix anode signal to be used as a  $\Delta E$  signal.

A preliminary run was taken of the  ${}^{24}\text{Mg}(d, {}^6\text{Li}){}^{20}\text{Ne}$  reaction. Angular distributions were taken from  $10^\circ$  to

$40^\circ$  in  $5^\circ$  steps for the  $0^+(g.s.)$ ,  $2^+$  (1.63 MeV) and  $4^+$  (4.25 MeV) levels. The data are presently being analyzed, and will be compared to reaction calculations when the analysis is completed.

Both single telescope and coincident telescope data for the final state  ${}^6\text{Li}$  and  $\alpha$  particles from  ${}^{10}\text{B}+\alpha$  reactions with a thin  ${}^{10}\text{B}$  target and the 150 MeV IUCF  $\alpha$  beam have been obtained.

Preliminary analysis provides angular distributions for the  ${}^{10}\text{B}(\alpha, {}^6\text{Li}){}^8\text{Be}^*$  reactions which are similar to those previously published.<sup>1)</sup> Figs. 1 and 2 show the distributions and predictions from the code DWUCK for the ground state and 2.9 MeV  ${}^8\text{Be}$  state. Table 1 gives the DWUCK parameters used. All predictions are for  $L=2$ ,  $J=3$ .

Breakup data for the  ${}^{10}\text{B}+\alpha$  to  $({}^6\text{Li}, {}^6\text{Li}, d)$  and  $({}^6\text{Li}, \alpha, \alpha)$  final states indicate that the quasifree processes do not dominate the breakup cross section and that phase space or simultaneous breakup processes contribute overwhelmingly to the  $({}^6\text{Li}, \alpha, \alpha)$  final state cross section.

The ground state of  ${}^{10}\text{B}$ , which is  $T=0$ ,  $J^\pi=3^+$ , should have an appreciable component of the  $\alpha+{}^6\text{Li}_{2.18}$  cluster structure with orbital angular momentum  $L = 0, 2, 4$ .<sup>2)</sup> The pole graph of Fig. 3 depicts the  ${}^{10}\text{B}+\alpha$  quasifree scattering processes in which the transferred particle (labelled  ${}^6\text{Li}$ ) can be either a  ${}^6\text{Li}$  or a  ${}^6\text{Li}_{2.18}$ . These two modes can be distinguished by measuring the  $L=0$  and  $L=2$  components of the Fourier transforms of the  $\alpha-{}^6\text{Li}$  relative-motion wave function.

Table 1.  ${}^{10}\text{B}(\alpha, {}^6\text{Li}){}^8\text{Be}$  DWUCK Parameters

	V	r	a	W	$r_w$	$a_w$	$r_c$
$\alpha$	100	1.25	0.8	20	1.60	0.60	1.3
${}^6\text{Li}$	40	1.48	0.5	5	1.86	0.86	1.3

(Potential strengths in MeV, geometry parameters in fm)

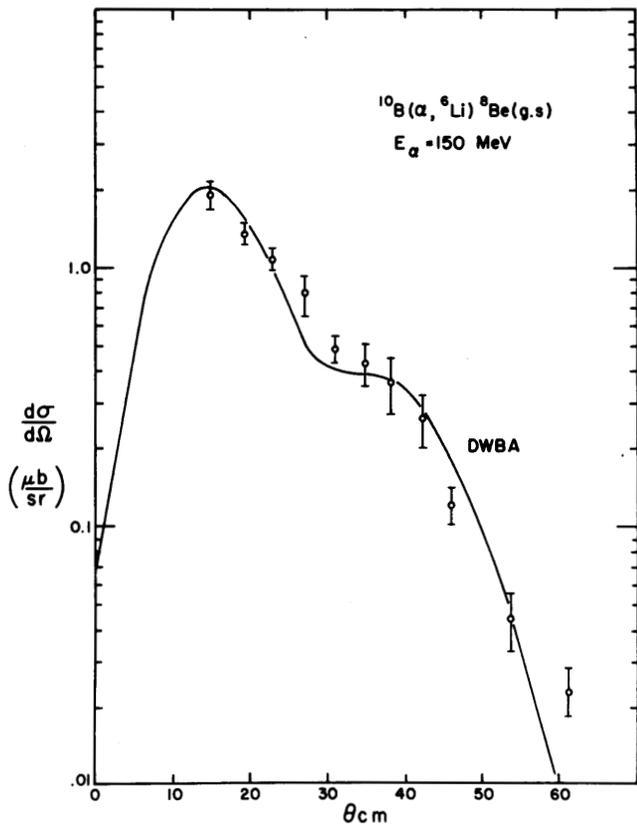

Figure 1. Angular distribution for the  $^{10}\text{B}(\alpha, {}^6\text{Li})^8\text{Be}(\text{g.s})$  reaction to the ground state. The shape of the predicted spectrum is not sensitive to  $V$  or  $W$  of  ${}^6\text{Li}$ , but is quite sensitive to the  $V$  of the  $\alpha$ -particle. The  $W$  of the  ${}^6\text{Li}$  affects the magnitude of the cross section which has been arbitrarily normalized to the data.

Any  $L=0$  component should be due to  ${}^6\text{Li}_{2.18}$  being the transferred particle. Fig. 4 shows part of the data and a PWIA relative cross section prediction. With the paucity of data, it is difficult to determine the  $L=0$  contribution, but the data suggest that the process is

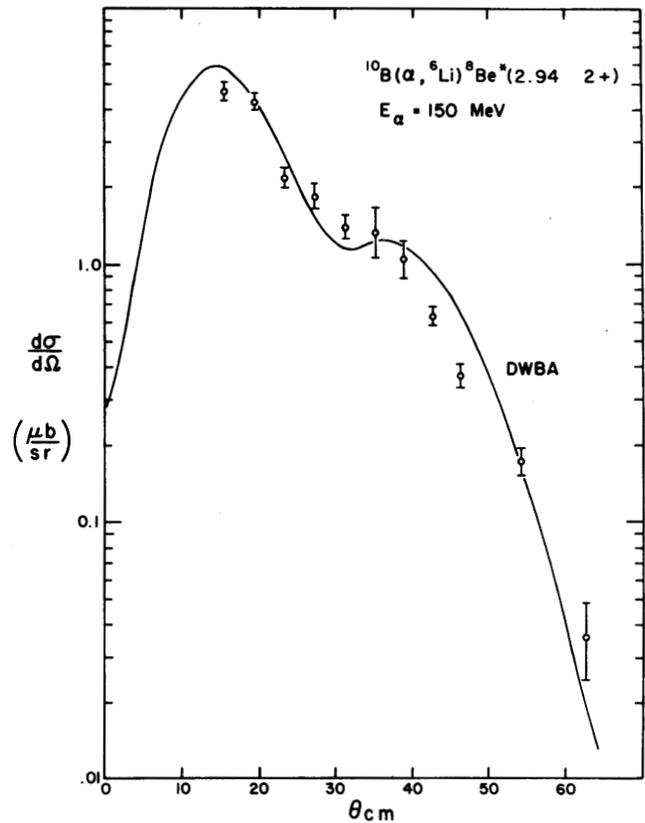

Figure 2. Same as Fig. 1., but for the  $^{10}\text{B}(\alpha, {}^6\text{Li})^8\text{Be}^*(2.94 \text{ } 2+)$  reaction to the 2.9 MeV state.

dominated by the  $L=2$  component and that some  $L=0$  contribution will be required to fit the data.
